

Filtering Results

You can filter which results are returned by most list endpoints (such as [List services](#)). You provide filter values as query parameters separated by `&`, like so:

cURL

```
curl --request GET \  
  --url 'https://api.render.com/v1/services?name=test-service&type=static_site' \  
  --header 'Accept: application/json' \  
  --header 'Authorization: Bearer API_KEY_GOES_HERE'
```

If a filter value includes reserved characters (such as spaces), make sure it's [URL-encoded](#).

For available filters, consult the reference page for each list endpoint.

Multi-value filters

You can provide multiple values for a single filter, separated by an *unencoded* comma (`,`). If you do, the endpoint returns results that match *any* provided value for that filter.

For example, this request fetches all services of type `static_site` *or* `web_service` :

cURL

```
curl --request GET \  
  --url 'https://api.render.com/v1/services?type=static_site,web_service' \  
  --header 'Accept: application/json' \  
  --header 'Authorization: Bearer API_KEY_GOES_HERE'
```
